

2022 Financial Year End Summary

The District ended 2022 with an \$8.3 million net gain, making it six years in a row with an increase in net position. The District’s strategic business model anticipates variability in net income over time due to significant variability in retail revenue sales and power supply costs. In the long run, the District sets rates sufficient to generate positive net income in order to cover operating expenses, power expenses, capital costs in excess of depreciation, and to make interest and principal payments on bonds.

As Chart 1 illustrates, the District’s net income (or loss) varies each year. This is a direct result of variability in power expense and retail revenues which are influenced by water flow through the dams, secondary market prices, and weather (a major driver of retail revenues). It is important to note that over the last seven years, the District has experienced wide variations on net income. Benton PUD’s combined net income for the same period was \$47.8 million.

Chart 1

The District maintains adequate reserves in order to handle volatility in revenues and power expense, as seen over the past several years. These reserves help Benton PUD respond to emergencies, provide stable rates, and help maintain Benton PUD’s credit rating from rating agencies. The District has used excess reserves that were generated in years of strong positive net income to maintain low retail rates, defer future rate actions, and defer future debt issuances.

With 2022 resulting in the sixth straight net gain, the District continues to meet its obligation to bondholders and internal planning requirements with a debt service coverage (DSC) ratio of 3.55 times. The DSC ratio measures the amount of net revenues that are available to make bond principal and interest payments. The DSC ratio is an important factor that is evaluated by rating agencies when assigning credit ratings (higher is better).

The District is contractually committed to its bondholders to maintain a DSC of 1.25 times. The District’s financial policies require that financial plans are set to achieve a ratio of at least 2.0 times. The DSC ratio has been over 2.0 times for more than a decade.

The District last issued bonds in Fall 2020, by issuing \$23.5 million in bonds to finance capital expenditures and refinance higher interest rate debt. The bond issuance resulted in reduced total debt service payments of approximately \$48,000 and \$20 million available for capital expenditures.

In 2022, Fitch and Standards & Poor's affirmed the District's current bond ratings at AA- and A+ respectively, due to strong management, solid financial metrics, and moderate debt levels. Moody's last affirmed its rating at Aa3 in 2020.

The following sections provide a background on the key factors that contribute to variations in the District's net income or (loss).

Retail Revenues:

Weather has a major influence on how much power customers use. This translates into how much revenue the District collects from its customers. The late Fall/Winter months of 2022 (January, November, and December) were on average about 7° colder than the 5-year average resulting in retail revenues higher than budgeted for those months. The summer months of the year (July, August, and September) were on average 3.2° warmer than the 5-year average resulting in higher revenues than budgeted for those months and ultimately contributed to the District's retail sales revenues being up \$3.8 million from the 2022 original budget projection.

One measure of how temperature affects power usage is a metric known as degree days¹. During 2022, heating degree days were 10% above the 5-year average. Cooling degree days in 2022 were 7.8% above the 5-year average. Variances in heating degree days influence energy consumption far more than variances in cooling degree days. As a result of variances in degree days, usage by the District's residential customers was above the average of the last ten years, as illustrated in Chart 2.

¹ A "Degree day" is the difference between the actual average temperature for that day and 65° F. If it is warmer than 65°, "cooling" degree days will result. If it is cooler than 65°, "heating" degree days will result.

Each degree over or under 65° is considered a degree day. For example, if the average temperature on April 1 was 55° degrees, you subtract 55 from 65 to get 10 so that day had 10 heating degree days. By adding the degree days for all the days in a month, it provides a way to compare the months to see how much colder or warmer each month was. In the months with a larger number of heating degree days (or cooling degree days), customers will likely have a higher bill.

Chart 2

Power Expense:

The District uses net power expense, power supply expense less secondary market sales, as a means to measure overall financial performance related to power supply management. The District’s net power supply expense increased by \$3.5 million (4.2%) in 2022 to \$87.5 million, primarily as a result of higher market prices, increased power purchases to manage daily loads, and hotter summer conditions than normal.

BPA Contracts

Approximately 85% of the District’s gross power is purchased from the Bonneville Power Administration (BPA). The District is a “Slice” customer of BPA and receives a percentage (or slice) of the total Federal Power System operated by BPA, which is largely made up of hydropower. Generally, the District receives more power than is used by its retail customers and sells the excess on the secondary market. Revenues from these “excess” secondary market sales are used to “buy down” customer rates. This is referred to as being “long on power.” Hydropower output can be volatile and varies based on the amount of water that flows down the rivers. The District manages the risk associated with the high degree of variability in power costs by proactively hedging future projected needs and maintaining adequate financial reserves.

Secondary Market Price

Secondary market prices over the past 10 years have remained relatively level until the last two years as illustrated by Chart 3. Historically the District was a net seller of power into the wholesale market and the net sales proceeds were used to partially offset power supply cost increases and ultimately help buy down retail rates. The District was a net seller of power into the market based on volume for 2022. However, the District was a net purchaser of power in the second half of the year when wholesale prices surged with an average cost of over \$200/MWh in December for example. The average price of market purchases was about \$150/MWh for 2022. The surge in market prices reflects the regions concern for resource adequacy as dispatchable firm generation is retired and replaced with intermittent resources. In the end, the District was a net purchaser based on dollars for 2022 and incurred an additional \$7.2 million in net power costs as compared to the budget.

Chart 3

Looking Ahead

As the District looks to the future, we are seeing an inclining long-term trend in residential retail growth of about 0.35%. Stream flows in 2023 are expected to be below average at 95%, which will reduce excess power to sell thus less revenue; however, the District anticipates secondary market prices to be above the 10-year average during the summer months based on forward price signals. The District is expecting net power expense to be above the original budget. As noted earlier, the District receives the majority of its power from BPA which continues to see increasing cost pressures. The District is not planning a rate increase in 2023.
